

Low-grade Squamous Intraepithelial Lesion (LGSIL)

When the cervical screening test shows the occurrence of LGSIL, it means that the cells have mildly deteriorated. Since the progression from severe deterioration of cervical cells to cancer generally takes about 5 to 10 years, the condition does not pose any immediate threat, so please do not worry excessively.

The screening test cannot fully reflect the degree of deterioration of the cervical tissues. According to previous medical publications, out of 1000 women who are found in the preliminary screening to have mild deterioration of cervical cells, about 150 actually suffer from severe deterioration of cervical cells. For more accurate diagnosis, a colposcopy should be performed to extract cervical tissues for further examination.

What is colposcopy?

Colposcopy refers to the examination of the vagina and cervix using a magnifying glass. The examination procedure can be performed at clinics without anaesthesia and will take about 10 minutes.

Procedures

The doctor will insert the colposcope, stain the vagina and cervix with special medicinal solution and then use the magnifying glass to identify any abnormal lesion. If abnormal lesion is found, the doctor will use an equipment to extract a small piece of the tissue and send it to the laboratory for further analysis. The whole process is painless and therefore there is no need to worry about the procedure.
